I. FISCAL COSTS ASSOCIATED WITH NATO AND EU ACCESSION¹

A. Introduction

1. Poland is currently preparing to join both the North Atlantic Treaty Organization (NATO) and the European Union (EU). In line with its new commitments, Poland is likely to incur significant budgetary costs, though these are difficult to quantify because the exact nature of Poland's obligations in joining NATO and the EU are still uncertain. Membership in both NATO and the EU will entail a relatively long accession period, probably stretching out to 2015 for NATO accession, and possibly equally long for fully phasing in all aspects of EU accession, such as consistency with the EU's common agricultural policy.

B. Fiscal Costs Associated with NATO Accession

2. As part of its accession to NATO, Poland has prepared a plan to harmonize its armed forces with NATO's forces. Over the 1998–2015 period, the main goal is to modernize the armed forces, which would entail reducing the number of soldiers from 250,000 to 180,000, and upgrading military equipment and infrastructure. Under this plan, the number of officers would decline while the number of noncommissioned officers and professional staff would increase. There would also be a reduction in administrative divisions and some equipment purchases. Army infrastructure would decline, and naval and air infrastructure would increase.

3. Altogether, the military budget is divided into two main components: core national defense and secondary services, such as health care and social security. The core services comprise 72 percent, secondary services, 20 percent, and other costs, 8 percent. The plan commits Poland to spending no more than 2.4 percent of GDP per year on the military over the accession period, which would require a slight increase in spending over current levels (Table 1). Spending is roughly 2.1 percent of GDP in 1998. The costs associated with NATO accession can be divided into two groups: indirect costs associated with upgrading equipment and infrastructure, and direct costs. Indirect costs would likely be borne in any event so it is difficult to allocate them specifically to joining NATO. Direct costs include those associated with improving interoperational relations and training with other NATO countries; creating and maintaining Polish representations in NATO; creating a joint Polish, German, and Danish corps; and payment of Poland's contribution to the NATO budget. Costs related to the possible purchase of multitask aircraft have not yet been included in the budget, though savings elsewhere might free up funds for this purpose. There are no firm estimates of the costs of these aircraft yet.

¹ Prepared by Janet Stotsky.

C. Fiscal Requirements for EU Accession²

4. Under the Europe Agreement that Poland signed in 1991, Poland committed itself to reform its laws, regulations, and institutions in preparation for accession to the European Union (EU). There are relatively few formal fiscal requirements for Poland's accession to the EU. The main requirements relate to bringing Poland's regulatory and administrative structures into compliance with EU standards and also raising excise taxes on fuel and cigarettes so that these taxes achieve minimum levels mandated by the EU. There are, however, other fiscal reforms that Poland is likely to undertake as part of its accession strategy that could have significant budgetary implications.

Meeting EU regulatory standards

5. The main requirements are to bring Poland's regulatory and administrative structures into compliance with EU standards, especially in the areas of upgrading road systems and infrastructure for utilities, improving water treatment and quality, and reducing air pollution. The direct costs specifically related to EU directives on regulatory and administrative structures are estimated at US\$6.6 billion over the 1998–2000 period, according to a recent World Bank Country Economic Memorandum (CEM). This is equivalent to about 1.5 percent of GDP on an annual basis.

Transport

6. In the transportation area, harmonization with the EU will require Poland to strengthen main roads to handle heavy EU loads, to restructure the railways and cut subsidies to them, and to increase the taxes on motor fuels. In 1992, it was estimated that Poland might need to spend about US\$1.4 billion to strengthen its main international roads. Some of the improvements in the transportation infrastructure could be financed by higher fuel taxes if the government chose to dedicate these funds to this purpose, as is common in many countries. Reducing subsidies to loss-making railways would also ease fiscal burdens.

Environment

7. Poland already has a modern National Environmental Policy, which would, over time, harmonize its environmental policies with those of the EU. Nevertheless, meeting EU directives will be expensive, requiring substantial investments in both institutions and environmental infrastructure. The direct budgetary costs depend on whether the private sector picks up a share of the costs through higher user charges and the extent of EU subsidies for this purpose. Key areas for environmental legislation are:

² This analysis draws heavily from the World Bank, Country Economic Memorandum on Poland, June 1997.

Air pollution

8. The main reason for poor air quality is the discharge of smoke and particulate matter from coal combustion. The investments required to reduce particulate emissions to EU standards are estimated to cost US\$6 billion to US\$8 billion over 8 to 10 years and of sulfur dioxide pollutants, US\$4.2 billion over 15 years. Most of these costs would be borne by industry and households, though direct budgetary costs could arise from subsidies or tax breaks to industry and households to put in place less polluting technologies, especially in switching from coal to cleaner fuels.

Water quality and wastewater management

9. The largest investment is needed for improving water quality and wastewater management. The investments required to meet urban wastewater treatment provisions could total US\$11 billion to US\$14 billion over 15 years. Upgrading or installing treatment plants to meet basic secondary treatment standards could add US\$11 to US\$12 billion to this total over years.

Industrial pollution

10. There has already been a substantial decline in industrial emissions of air and water pollutants in Poland in recent years and complying with EU emission standards may not be difficult for most industries. A few industries, however, such as steel and paper, may face a heavier burden.

Oil, gas, and telecommunications

11. Poland is also likely to require investments in the oil, gas, and telecommunications sectors to ensure compliance with EU directives and regulations, but the budgetary implications depend significantly on the pace of privatization and other changes in the regulatory environment. In the energy area, the EU requires improvements in the regulatory framework, price transparency, restrictions on state aid, and harmonization of indirect taxes. In the telecommunications area, the EU also requires a liberalized regulatory framework.

Taxes

12. The main outstanding area for tax harmonization is excise taxes on fuel and cigarettes as Polish rates for some goods are below minimum EU rates for members. The EU minimum rate for gasoline is currently about 70 percent higher than the Polish rate and for diesel, 170 percent higher. The EU requires the excise tax on cigarettes to comprise at least 57 percent of the retail price and in Poland, it is currently 40–50 percent. The elimination of the import surcharge in 1997 removed one other outstanding issue, though Poland remains committed to a process of tariff reduction as part of trade agreements signed with other

European countries. Apart from ensuring compliance with the EU Sixth Directive on indirect taxes, Poland does not need to make significant adjustments to its indirect or direct tax system for accession to the EU, though there remain areas of weakness in tax structure and administration that ought to be a priority for reform as part of Poland's general strengthening of fiscal management and policy.

Other areas of restructuring

State enterprises

13. Enterprise restructuring is another important component of reforms. Although there are no formal requirements for reform of state enterprises for EU accession, it may be necessary for the government to assist in restructuring certain state enterprises to enable the proper development of these industries in the economy.

Agriculture

14. In agriculture, Poland falls considerably short of EU quality and technical standards. The effect on the budget of EU accession is hard to quantify given that the system of agricultural subsidies in the EU is excessive and is likely to be reformed in the future. Agricultural subsidization in Poland was 15 percent of value-added in 1993, compared with around 50 percent in the EU, according to the OECD. This would suggest that Poland (or the EU) might have to incur costs to raise Poland's level of support to make them consistent with EU levels. However, the EU intends to reduce its subsidies for agriculture, which should make Poland's convergence with EU levels easier to achieve. It is also possible that Poland and other Eastern European countries will be exempted from EU standards in the agricultural area. The direct costs in the agricultural area are mainly the administrative costs of implementing all of the directives and a small extra cost to the farmer's pension fund, KRUS, if farmers take earlier retirement.

Structural funds

15. Poland will likely be eligible for substantial EU structural funds, possibly on the same magnitude as those available to Greece and Portugal (about 2.5 percent of GDP), though this will depend in part on whether Poland develops the institutional capacity to absorb these funds. One potential use could be to meet the costly environmental compliance requirements of the EU. Another use could be to support institutional harmonization with the EU and the training of civil servants in public administration.

Fiscal implications

16. The CEM summarizes the budgetary implications of the main reforms (Table 2). The main direct costs specifically related to EU directives are for improvements to the transpor-

tation infrastructure (US\$1.3 billion), air pollution abatement (US\$0.7 billion), water and wastewater treatment (US\$2.5 billion), and infrastructure for the underground storage of gas (US\$2.1 billion). These dollar-denominated amounts are converted into a share of projected GDP over this period, using the exchange rates and nominal GDP figures in the medium-term. The direct costs specifically related to EU directives total US\$6.6 billion over this three-year period. This is equivalent to about 1.5 percent of GDP on an annual basis.

17. There are also likely to be significant benefits to the overall health and well-being of the population through improvements in environmental quality, and to the economy through improvements in the transportation and commercial and industrial infrastructure, and through reform of loss-making state enterprises.

D. Conclusion

18. Poland's accession to the EU could result in fiscal costs in certain areas, especially in upgrading the infrastructure in transportation and utilities, and improving the environment. The legislative reforms and the establishment of the regulatory and administrative structures are also likely to entail costs, though these costs are more difficult to quantify.

Table 1. Poland: Fiscal Costs of NATO Accession (in 1998) 1/

| | | |
|----------------|--|--|
| Total costs | All military operations | No more than 2.4 percent of GDP per year (US\$3.3 billion) |
| Indirect costs | Upgrading equipment and infrastructure | Difficult to attribute the amount related to NATO |
| Direct costs | Improving interoperational relations and training | Zl 312 million (US\$82.8 million) |
| | Creating Polish representations in NATO | Zl 15.8 million (US\$4.2 million) |
| | Creating a common Polish, German, and Danish corps | Zl 28 million (US\$7.4 million) |
| | Polish contribution to the NATO | 2.5 percent of the NATO budget budget no earlier than 199 (roughly Zl 140 million or US\$34.3 million in 1999) |

II. DIRECTIONS FOR FISCAL MANAGEMENT AND RESTRUCTURING IN POLAND³

A. Introduction

19. During the pretransition period, Poland had a system of government characterized by a strong state government with extensive powers, and local governments with little independent expenditure or revenue powers. Since 1990, Poland has been engaged in extensive fiscal restructuring. Two themes underlie recent reforms in fiscal management and intergovernmental relations. First, at the state budget level, the institutions for financial management, inherited from the pretransition system, are poorly suited to the requirements of a market economy, particularly the cumbersome and decentralized system of management of the state budget. One consequence of these institutional arrangements has been a persistent problem of expenditure arrears, most notably, in the health care area. A critical issue that Poland must address in the next few years is how to improve the management of the state budget both to achieve a reduction in the state budget deficit and to ensure a high level of public service provision. Second, with respect to intergovernmental relations, movement from a system of total reliance on the state government toward a system of decentralized local governments has been guided by the notion that this would improve the provision of public services. There is still considerable uncertainty as to how many levels of government would be most effective in Poland and the ultimate evolution of the intergovernmental system.

B. Current System

20. Poland's state government consists of a central administration, mainly organized into powerful ministries, and geographic units, divided into 49 voivods and 267 rayons. The basic unit of local government is the gmina, of which there are 2,489. Warsaw consists of 11 gminas while all other cities and towns consist of only 1 gmina.

21. The state government's main responsibilities are for national defense, income transfers, the social insurance system, health care, higher education, state roads, and the police and judicial system. The state relies heavily on personal income and payroll taxes, corporate profits tax, a value-added tax, excises, trade duties, and nontax revenues. The gminas' main responsibilities are for primary education, local roads, communal services, and basic utilities, such as water and sewerage. Gminas rely primarily on the local property tax and an array of smaller tax and nontax sources.

22. The government is currently considering several major reforms in the intergovernmental system. As part of the proposed health care reform, state primary and secondary (nonspecialized) health agencies, now managed by voivods, would become autonomous though they would still be funded primarily by state tax revenues. Voivods would be consolidated into perhaps 12 regions, which would supervise the autonomous health

³ Prepared by Janet Stotsky.

agencies. The government is also considering the creation of a middle tier of government, termed powiats, which would be independent from both the state government and gminas, and these would replace rayons. There would be about 320 powiats. The expenditure responsibilities are envisioned to be roughly comparable to counties in the United States and would include authority over secondary schools, some health services, and some roads. There is not yet any identified means of financing powiats, since the other levels of government are reluctant to cede revenue sources to powiats.

23. In order to achieve sustainable, noninflationary growth, it is important that the overall general government deficit be reduced over the medium term. It is thus essential that policies at the local government level contribute to reducing the state budget deficit, and that the reforms within the state budget and among the different levels of government not threaten the ultimate objective of a balanced budget.

C. Health Care Reform⁴

24. As part of the process of economic transition, Poland's system of health care provision has been under stress. Poland has not experienced the serious drop in spending on health care and in life expectancy that some other transition economies have experienced.⁵ Nevertheless, the health care system is poorly structured and does not provide the quality of care that is typically found in a developed economy.

25. As an important step toward modernizing its health care system, in 1997, Poland enacted the General Health Insurance Law, which would create a health financing system based on public and private insurance, to go into effect in 1999. Because of inconsistencies and unresolved issues in the law, the Ministry of Health has now drafted an Amending Act. The precise plan for implementation is still in flux. Under the proposed new system of health care, governmental health units would be turned into autonomous health units and directors of these units would sign contracts with the state. The aim is to establish a system by which all units would have access to public finances and competition between them would lead to an improvement in quality.

26. A main component of the reform is the creation of a public insurance scheme. Under the proposed system, Poles would be able to choose from regional (public), trade, and private insurance funds, and which doctors and hospitals to use. The authorities describe the plan as one in which "money would follow the patient." The division of the insurance market into

⁴ This discussion substantially benefited from the analysis of a World Bank Health team that visited Poland in January 1998.

⁵ Ellen Goldstein, Alexander S. Preker, Olusoji Adeyi, and Gnanaraj Chellaraj, "Trends In Health Status, Services, and Finance: The Transition in Central and Eastern Europe," World Bank Technical Paper, No. 341, 1996.

distinct public and private insurance options exists in a number of countries. One advantage of choice is that it could create an atmosphere in which health care providers would be more likely to compete to provide a high level of care. The disadvantages are that it could be more administratively complex, particularly if it combines both public and private elements, and it could require a higher level of regulatory oversight. The proposed amendments deal only with oversight of the regional insurance funds.

27. The proposed insurance funds would be supported by a tax on personal income. The proposed amendments provide for a health insurance premium defined as a given percentage of income, which could change over time. The tax would apply to income at a flat rate.⁶ The tax would be offset against personal income tax liabilities, so that there would be no net increase in tax.⁷ For taxpayers who are not subject to the personal income tax, the government would make a payment on their behalf.

28. The proposed financing mechanism raises several important issues. First, while dedicated payroll taxes for health insurance are common in Europe, it is questionable whether it would be wise to introduce a dedicated income tax for health insurance in Poland in light of the already very high payroll tax burden to support social insurance programs. Dedicated taxes that are linked to income (such as the proposed tax) build automatic inflation into health care appropriations in the budget. The proposed amendments allow the Board of the Union of Health Funds to increase the percentage contribution rate, even without the concurrence of the Ministry of Finance. To a possibly large extent, this removes the determination of the level of health care spending in the budget from the general considerations that apply to other competing uses of public funds. In an environment where the state budget is faced with a difficult challenge to rein in public spending, this built-in increase in health care appropriations in the budget would only make this task more difficult. And since, according to the proposed amendments, any increase in the taxes dedicated to health insurance premiums must be matched by an equal reduction of personal income taxes, this would make difficult the achievement of other budget goals (though, presumably, there is nothing to stop the Parliament for legislating an increase in other taxes or the personal income tax for "other" reasons). The proposed amendments do not indicate what would be the relationship between the proposed financing and the expenditure needs.

⁶ The amendments are unclear as to whether the income would be gross or net as defined in the personal income tax law or just wages, as is typically found in other European countries.

⁷ The amendments are also unclear as to how this offset would work, whether through a credit or some other means. The amendments do not specify what would happen if the health insurance premium were greater than the personal income tax liability, if, for instance, the premium were levied on gross wages and net taxable income were considerably smaller than gross wages.

29. Second, the proposed financing provides little in the way of incentives for health care providers to contain the growth in health care expenditures. Providers would be paid on a fee for service basis, which gives them incentives to offer more services to patients than might strictly be necessary. Hospitals would be reimbursed under a "global" budget, which could lead to a decline in the quality of care, if hospital management is poor. Drawing upon international experience, there are several ways in which the health care system could provide strong incentives for cost containment. For hospital reimbursements, the development of a system of diagnosis related groups (DRGs) has been successful in the United States in slowing hospital cost inflation. Under this system, hospitals are not reimbursed at cost for the treatment of patients. Instead, diseases and treatments are divided into related groups and hospitals are reimbursed for patient care depending on the diagnosis and treatment. Also, it may be desirable for Poland as part of the reform to develop a notion of core health care services that would be provided on demand to the population and another set of services that would be provided with limits, and to determine the appropriate level of technology that would be consistent with expected demand. Finally, one important method of controlling health care cost growth is to impose some marginal cost on the patient of additional treatment through copayments and deductibles. The proposed financing mechanism imposes no direct marginal cost at all on the patient since any increase in the premium is offset by a decrease in the personal income tax liability (though the proposed amendments do allow for the possibility of requiring a copayment). There may, however, be indirect costs if other taxes rise or if expenditures on other public services are cut.

30. Third, the proposed reforms only partly address the potential problem with adverse selection that is common in insurance markets. Trade and private insurers are likely to try to attract only the healthier and higher income elements of the population. As a result, regional insurance funds are likely to end up with a disproportionate share of the least healthy people, which is likely to increase their costs relative to the other funds. Although the financing of the system builds in an equalization mechanism for transferring money to funds that are facing deficits, it is unclear that the transfers would be sufficient to ensure that people covered by the regional funds receive the same quality of care that those covered by the other funds receive. This adverse selection may make it difficult to establish a set of norms for average costs of treatment, which are important in setting goals to contain the growth of costs (such as, for instance, under a system of DRGs).

31. Fourth, the proposed amendments obligate the state budget to extinguish the debts of public health care establishments prior to concluding agreements with the health funds. As previous efforts with eliminating health care arrears attest, paying off debts alone does little to impose discipline on health care establishments or prevent a recurrence of this persistent problem.

32. The proposed system of health care provision offers some improvements over the current system, but it does not satisfactorily address the fiscal burden of health care. Shortcomings in the design and financing of the proposed system should be addressed before the system is implemented.

D. Restructuring the Intergovernmental System

33. The intergovernmental system in Poland is evolving in other dimensions as well. One important change is the devolution of responsibility from higher to lower levels of government for some public services.

Expenditure assignments

34. From an efficiency perspective, there are certain advantages of more decentralized forms of intergovernmental fiscal relations. A federal system is likely to be more sensitive to local differences in preferences. It is thus appropriate to devolve responsibility for some expenditure decisions to lower levels of government to reflect local preferences. International experience would suggest that for countries such as Poland, there is some scope for decentralization. One disadvantage of a more decentralized intergovernmental system is that it typically leads to greater inequalities between wealthier and poorer localities, though most intergovernmental systems try to address these inequalities through shared revenues and intergovernmental grants.

35. The main advantage of creating a middle level of government is that it could more efficiently provide public services that have spillovers extending beyond individual localities. The government should reallocate certain local functions with spillovers to this middle level and then provide financing by a combination of shared state or local taxes, user charges, and grants from the state government. Apart from the introduction of a new middle level of government, there is a need to consolidate the smallest of the gminas into larger local entities to achieve economies of scale in public service provision.

Revenue assignments

36. Assigning expenditures to lower levels of government raises the issue of how to finance those expenditures. There are persuasive arguments linking the provision of local public services with local financing.⁸ Local governments in Poland rely on several sources of revenue including: own-source taxes; a share of the personal income tax collected by the central government; a share of the corporate income tax collected by the central government; grants and transfers from the central government; and local fees and user charges. By international standards, the own-source revenue of local governments in Poland is quite low. Strengthening the Polish local revenue system would contribute to government accountability by more closely linking the decision to spend with the decision to raise revenues to pay for that spending.

⁸ A distinction also needs to be maintained between the assignment of the revenues of a particular tax to a level of government and the assignment of the responsibility to collect that tax. It may be more efficient and effective for a higher level of government's tax administration to collect the tax.

37. The local property tax is in many countries the mainstay of local finance. The property tax is an effective tax for local governments to use because it is levied on a relatively immobile tax base. The more mobile the tax base, the greater the risk that interjurisdictional differences in tax burdens would cause taxpayers to move to reduce their tax burdens, though to the extent that taxpayers perceive a link between their local taxes and the supply of local public goods, they may be less likely to try to avoid the tax. The main local tax in Poland is property taxes on real property. There is no up-to-date register of ownership and market valuations for property in Poland. Hence the existing property tax relies on specific charges levied on area. Modern property taxes are based on registers, which are regularly revised, and the tax is levied on an ad valorem basis on property value, typically at an effective rate of 1–2 percent. Poland plans to implement a property tax based on market valuation for property in the near future, though there remains political opposition to strengthening this tax.

38. Shared revenues from the personal income tax and corporate income tax are a major source of revenues for local governments. All gminas receive a predetermined share of personal income tax and corporate income tax revenues. In 1998, the gminas are receiving 17 percent of personal income tax revenue collected in the locality, an increase over 16 percent in 1997. In the past, the gminas' share of personal income tax revenues was proportional to population and this method has been only slowly phased out for gminas with low incomes, which have been hit hard by the switch to a transfer based on income earned in the community. In 1998, the gminas are also receiving a 5 percent share of the corporate income tax based on employment of each corporation in a locality.

39. The shared personal income tax collected by the central government is another way of strengthening local revenues in the short term. Transferring a fixed share of a centrally administered tax such as the personal income tax to the localities is practiced in other countries. The shared tax could, however, be made more flexible. Each local government could be allowed to set its own tax rate (on the tax base set by the central government) and therefore be accountable to its citizens for this tax burden. Allowing local governments to "piggy back" on existing taxes is another alternative. Depending on the degree of autonomy granted as regards setting the additional rates for these taxes, there is the possibility both of straining administrative capabilities and compromising the competitiveness of some regions.

Intergovernmental grants

40. Grants from the central government are also an important component of local public finance in Poland. Transfers from the state budget consist of four types: (a) a general subvention, equal to 0.9 percent of planned revenues. Part of this subvention is an equalization subsidy, which helps equalize the potential of poorer gminas to pay for public services. It is given to gminas where the per capita income is less than 85 percent of the total and the equalization covers 90 percent of the difference between 85 percent and 100 percent; (b) an educational subsidy, categorized under the general subvention, equal to 7.5 percent of planned revenues. This subvention compensates for the transfer of responsibility for primary education

to gminas; (c) targeted subsidies which can only be spent on targeted projects. Voivods establish the projects and amounts. The list of possible projects is extensive, including investments, social assistance, and other governmental purposes; and (d) a road subsidy, which replaced the local road tax in 1997.

41. Many federal systems use equalization grants to "level the playing field" for the range of jurisdictions.⁹ However, equalization grants are technically difficult to implement because they entail determining whether the objective is to equalize the taxable capacity or actual public service provision of differing localities and then to devise an appropriate measure of taxable capacity, which is not easily manipulated by the local administration—for example, if the indicator of taxable capacity is based on a limited set of taxes, there is an incentive for lower level jurisdictions to raise revenue by using taxes not included in the indicator base. Finally, equalization grants in many countries often prove to be politically contentious.

Local government borrowing

42. Gminas are, in principle, free to borrow without central government interference or control. In practice, however, most local governments have been reluctant to incur debt, even for capital purposes, reflecting a combination of prudent behavior and the absence of an established mechanism and market for issuing this debt. The localities face a limit that the sum of interest, principal and payments for debt guarantees cannot exceed 15 percent of total revenues, including intergovernmental grants. Although no locality has yet reached this limit, the use of municipal debt has begun to grow rapidly, with the outstanding amount of municipal debt nearly doubling from Zl 447 million to Zl 897 million, from 1995 to 1996 (still, however, only ¼ percent of GDP).¹⁰ This debt is likely to continue to grow in the next few years as localities face pressures for substantial investments in infrastructure and other capital projects. Since reliance on market forces alone at this stage of transition may not ensure that sufficient discipline is maintained on subnational borrowing, it is important to impose formal constraints as well. Subnational external borrowing should be strictly limited to avoid an accumulation of external debt by local governments, which may require a state bailout in the event of a severe economic downturn or fall in the exchange rate.

⁹The case for equalization grants presumes that the instruments available to the central government through tax and transfer programs, are insufficient to achieve overall distributional objectives.

III. NEW DEVELOPMENTS IN MONEY DEMAND IN POLAND¹¹

A. Introduction

43. Several recent developments have complicated the analysis and forecasting of money demand in Poland. Foremost has been the rapid growth of broad money, which has exceeded the projections of most standard money demand models during the past couple of years, and especially during 1997. Real money growth was negative in 1993, in the range of 7–10 percent per year during 1994–96, but was about 14 percent in 1997. The fact that this acceleration in money growth has been accompanied by continuing disinflation suggests that there probably has been some general upward shift in money demand. Is there statistical evidence of such a shift in the money demand process in recent years? If so, what factors seem to explain this shift?

44. New institutional developments in Poland also complicate the analysis of money demand. During the past couple of years, for example, there has been extremely rapid development of the government securities market, especially the treasury bill (T-bill) market. Turnover in this market has been doubling every 15–18 months, with average monthly turnover increasing from less than 20 billion zloty per month in June 1996 to over 50 billion zloty in recent months—almost US\$1 billion per day. As this market has grown deeper, the government has actively encouraged treasurers of large enterprises to substitute T-bills for bank deposits (because their return is higher), a move that in theory should work to reduce money demand. Is there statistical support for this hypothesis? Might this be a factor causing actual money demand to be lower than the authorities realize and hence, a potential source of inflation?

45. This note explores these issues. The first section provides an overview of trends in money demand in Poland in recent years. The second section examines the statistical problems of existing money demand equations and describes a quarterly money demand equation that does a decent job of tracking money demand over recent years. The third section attempts to quantify the possible effects of the fast growth in the government T-bill market on money demand by enterprises. The paper argues that there is statistical corroboration for the hypothesized substitution effect, but finds that it is relatively small, especially in the face of strong overall household demand for money.

B. Main Trends in Money Demand

46. Although Figure 1 shows that broad money has displayed a general upward progression over the past 6 years, it is when the series is expressed in real terms, as in Figure 2, that a sharp acceleration starting in 1995 becomes most evident. Actually, two periods of rapid acceleration of broad money demand appear on careful inspection—one

¹¹Prepared by Robert F. Wescott.

Figure 1. Poland: Broad Money (M2)
(In billions of zloty)

Figure 2. Poland: Real Broad Money (M2)
(January 1992= 100)

period from early 1995 until late 1996, and a second phase of even more rapid growth starting in late 1996 and continuing throughout 1997.

47. Figure 3 shows which components of broad money have been chiefly responsible for these developments. Foreign currency deposits have been trending downward as a share of GDP over the period since 1995, meaning that demand for zloty money has been driving money growth. Specifically, as Figure 4 makes clear, it has been household deposits that have been fueling the growth of broad money. These deposits increased from roughly 8 percent of GDP in the early 1990s to over 15 percent in 1997. Zloty currency demand and enterprise deposits have been roughly flat as a share of GDP over the entire 1992–97 period.

48. This brief review of the main trends in money demand suggests that it would not be surprising to find evidence of a structural break in the money demand process around 1995, and that it may be difficult to explain recent money demand behavior based upon the historical experience of the first half of the 1990s. It also shows that virtually all of the growth in money has come from household zloty deposits. There has been a gradual remonetization of the Polish economy over this period, but as Figure 5 illustrates, the ratio of M2 to GDP in Poland remains much lower than in the Czech Republic, although it is about the same as the ratio in Hungary.

C. Evaluating Money Demand Equations

49. Given the sharp increase in real money demand that began in 1995, it indeed is the case that simple quarterly equations estimated over periods such as 1992–97 do have a difficult time explaining recent money demand trends. In fact, most standard models of Polish aggregate money demand do display Chow–test evidence of a structural break at the end of 1994 or during 1995.¹² For example, a typical money demand equation that explains the log of real money demand as a function of the log of industrial production and the delta log of the consumer price index displays evidence of a structural break after the fourth quarter of

¹²In discussions in December 1997, NBP officials confirmed that their main quarterly money demand equations that have been relied upon in the past for forecasts of money demand displayed evidence of structural breaks—with the break indicated between early 1995 and early 1996.

Figure 3. Poland: Broad Money and Components (M2)
(In percent of GDP)

Figure 4. Poland: Components of Zloty Money
(In percent of GDP)

Figure 5. Poland, Hungary, and Czech Republic: Ratio of M2 to GDP

1994.^{13, 14} Particularly worrisome is the fact that this and similar equations consistently underpredict money demand from late 1996 through the end of 1997.

50. Such a consistent underprediction of money demand suggests that the simple model described above is misspecified, and that additional variables might be having an effect. Two changes in particular might have had a profound effect on Polish money demand behavior in recent periods: the rapid increase in real bank deposit rates from highly negative levels a few years ago to highly positive levels now, and the steady firming of the zloty. Higher real bank deposit rates make Polish households more likely to view bank deposits as a form of wealth and therefore more desirable, while the firming of the zloty in international currency markets causes zloty deposits to be seen as a more reliable store of value and therefore more worth holding. The swing in bank deposit rates has been particularly sharp: in mid 1995 such deposit rates were between minus 4 percent and minus 7½ percent in real terms, whereas by late 1997 they had increased to a positive 6½ percent.¹⁵

51. An augmented aggregate money demand equation, presented in Appendix I, adds these variables to the basic money demand equation and finds that they do improve the explanatory power of the model, especially when the estimation period is from the first quarter of 1995 to the end of 1997. The following table provides a decomposition of real money growth in 1997, based upon the right-hand-side variables in this augmented model:

1997 4th Quarter on 4th Quarter Percent Change

| | |
|---|------|
| Total Real M2 Growth | 13.9 |
| due to change in IP | 6.5 |
| due to change in CPI | 4.1 |
| due to change in real bank deposit rate | 3.9 |
| due to change in zloty vs. parity | -0.6 |

¹³For further description of such models of money demand in Poland, see "Money Demand in Poland," Attachment II, IMF Staff Country Report No. 97/33, April 1997, pp. 174–88.

¹⁴The simple model described here was judged to be the most robust of numerous models that were tested. Among the explanatory variables tested were the log of industrial production, the log of real retail sales, the delta log of the CPI, interest rate spread variables, etc. For the model selected, the F statistic for a Chow test for a break after 1994–Q4 was 19.3 (critical value for 0.05 significance 3.05 and for 0.01 significance 4.89)—meaning that the evidence of a break was highly significant.

¹⁵Inflation in these real estimates was defined as the backward-looking 12-month change in the CPI.

52. This analysis suggests that rising real interest rates contributed in an important way to the rapid increase in real money demand in 1997. Real interest rates are very high now, however. As real interest rates stabilize or decline during the course of 1998 and 1999, as is expected, it is likely that there will be a significant slowdown in the rate of growth of money demand. This suggests that the Polish monetary authorities need to be cautious in supplying liquidity to the banking system during the next couple of years to help make sure that a mismatch of money supply and money demand does not occur. Such a mismatch could lead to an inflationary bias in monetary policy.

D. Do Enterprises Treat Government Securities as a Substitute for Money?

53. Although aggregate money demand has been increasing rapidly as described above, the fast growth of the Polish T-bill market raises the question of whether enterprises might be substituting these instruments for traditional demand deposits. Such a development would tend to work in the direction of diminishing money demand.¹⁶ Do Polish enterprises treat government securities as a substitute for money? If so, how large of an effect does the growing T-bill market seem to have on enterprise money demand? This section attempts to answer these questions via an econometric approach. Because of severe data limitations, however, the results of this analysis should be considered more as a statistical illustration of a possible effect, rather than as firm proof of a relationship.

Methodology

54. In order to test whether enterprises might be substituting T-bills for bank deposits, a three-step methodology was employed. The first step was to estimate a basic money demand equation for enterprise demand deposits, with the log of enterprise bank deposits minus the log of CPI inflation (i.e., the change in the real demand for this type of deposit) estimated as a function of the log of real retail sales.¹⁷ The residuals for this equation were then examined with the supposition being that this standard model would tend to overpredict enterprise money demand for recent periods, especially the quarters of 1997. This is because if T-bills were increasingly substituting for enterprise demand deposits, there should be a growing gap in this simple equation's ability to predict these deposits, with systematic overpredictions in recent periods. The amount of overprediction would then be considered the unexplained portion of enterprise deposit demands that might be due to the increased use of T-bills.

¹⁶That is, the partial effect would tend to be negative for money demand by enterprises, and hence for overall money demand.

¹⁷A number of different variables and specifications were tested, including industrial production in several formulations, the spread between the interest rate on T-bills and bank deposits, etc., but the simple money demand function described above provided the most robust equation.

55. The second step was to then augment the basic money demand equation with a variable or variables to quantify the growth and attractiveness of the T-bill market. Among the variables tested were the spread between the interest rate on T-bills and bank deposits, the outstanding volume of T-bills, and a variable that measured the turnover volume of T-bills in the secondary market. In theory, a larger spread between the interest rate on T-bills and bank deposit rates, a larger volume of T-bills, and a larger T-bill turnover volume (indicating a more liquid market) would be expected to make the holding of T-bills more attractive and the holding of bank deposits by enterprises less attractive. Based upon statistical results, the T-bill turnover volume was judged to be the best way to quantify the extent to which T-bills might substitute for bank deposits.¹⁸ This variable would have to enter with the proper theoretical sign (negative, meaning that more T-bill turnover would mean less demand for bank deposits), and be statistically significant. The R-bar squared for this augmented equation would also have to be higher than it was for the basic equation to prove that its overall (corrected) explanatory power was higher.

56. The third step was to compare the residuals for this augmented equation with the residuals from the basic equation. Presumably, this more complete model of enterprise bank deposit demand would show smaller residuals on average, and in particular, smaller residuals in recent periods. The improvement in the forecast would then be considered a measure of the degree to which T-bills substitute for enterprise bank deposits.

57. The basic and augmented models are presented in Appendix II. Note that both models feature variables that had the proper theoretical signs and that were statistically significant. Several alternate specifications of the model were attempted that had theoretical support, but they did not produce significant results. As a general caveat, it should be remembered that estimating demand functions for components of money demand has been shown by Begg, *et al.*, to be unreliable for transition economies.¹⁹

¹⁸The coefficient on the interest rate spread variable was not found to be statistically significant, so this variable was not used. The variable measuring T-bill turnover in the secondary market was judged to be a better variable than the outstanding volume of T-bills, because it was judged to better capture the liquidity aspects of the market—something that should be important to corporate treasurers thinking about substituting T-bills for bank deposits.

¹⁹See David Begg, Linda Hesselman, and Ron Smith, "Money in Transition Economies: Do We Know Much Yet? Evidence from Central and Eastern Europe," IMF Manuscript, 1996.

Results

58. Over the first three quarters of 1997, the average overprediction of the basic equation was 0.03 in log terms (0.90 billion zloty) and the average overprediction with the augmented equation was 0.00667 in log terms (0.27 billion zloty):

| | |
|---|------------------|
| Average actual enterprise bank deposit demand, 97Q1–97Q3: | 30.10 Bil. Zloty |
| Average predicted using basic equation, 97Q1–97Q3: | 30.99 Bil. Zloty |
| Average predicted using augmented equation, 97Q1–97Q3: | 30.37 Bil. Zloty |

59. That is, the augmented equation with the T-bill turnover variable did lead to a lower standard error for the regression equation as expected (by 0.62 billion zloty) and did make the forecast more accurate, as hypothesized above. Even the basic equation, however, predicted demand that was within 0.9 billion zloty of actual demand on average during 1997. This suggests that although this substitution effect (away from enterprise money demand and toward T-bills) has been statistically significant, the effect has been rather small. Overall, it seems to have been overwhelmed by the extremely rapid growth of money demand by households.

**AUGMENTED MONEY DEMAND EQUATION WITH REAL BANK DEPOSIT RATE AND
ZLOTY EXCHANGE RATE VARIABLES**

Ordinary Least Squares

Quarterly data for 12 periods from 1995-Q1 to 1997-Q4

$\log(\text{fmb}) - \log(\text{pcpi})$

$$= 0.79410 * \log(\text{aip}) - 0.39739 * \text{dlog}(\text{pcpi})$$

(6.22546) (1.58184)

$$+ 0.00666 * \text{realdeprate} + 0.00199 * \text{zlotyvparity} - 4.69597$$

(2.16724) (0.83811) (7.76678)

Sum Sq 0.0012 Std Err 0.0132 LHS Mean -0.9799
 R Sq 0.9896 R Bar Sq 0.9837 F 4, 7 167.141
 D.W.(1) 3.0476 D.W.(4) 0.8869

Where:

fmb = broad money demand
 pcpi = consumer price index
 aip = index of industrial production
 realdeprate = real bank deposit rate, percent
 zlotyvparity = value of zloty vs. parity, percentage difference

Note: The zloty variable is not found to be significant, but it is retained on grounds that it has the right sign, a reasonable (though admittedly small) coefficient, and because its inclusion helps to make other variables more significant. Although the Durbin-Watson statistic suggests the possible existence of negatively serially correlated error terms, the actual residuals do not appear to be serially correlated. A host of interest rate variables that are often included in money demand equations (yield on 90-day T-bills, other spread variables, etc.) did not enter the equation with the correct sign or were statistically insignificant.

**EQUATIONS USED FOR TESTING THE EFFECT OF GOVERNMENT T-BILLS
ON ENTERPRISE MONEY DEMAND**

The basic equation for explaining enterprise demand deposits was:

Ordinary Least Squares

Quarterly data for 11 periods from 1995-Q1 to 1997-Q3

$$\begin{aligned} & \log(\text{fmb_de}) - \log(\text{pcpi}) \\ & = 0.51411 * \log(\text{ars_r}) - 4.94079 \\ & \quad (3.92840) \quad (8.04709) \end{aligned}$$

IV. MEASURING CURRENCY VOLATILITY IN POLAND²⁰

A. Introduction

60. Against a backdrop of financial market turmoil in Asia, the National Bank of Poland (NBP) continues to be concerned about highly volatile short-term capital flowing into Poland taking advantage of high spreads on zloty denominated debt. By refraining from frequent interventions in the currency market, the NBP is hoping to decrease the risk-adjusted foreign currency returns on zloty denominated debt resulting from a more volatile zloty exchange rate. But just how volatile is the zloty in currency markets? How can this volatility be measured? And is there evidence that the volatility of the zloty may be increasing over time?

61. Through the use of a variety of volatility measures, evidence is found in this paper that the recent turbulence in Asian currencies largely has been passed through to the zloty by the NBP, causing volatility to increase. Large spikes in zloty volatility are found around the times of turbulence in the Asia markets in the summer and fall of 1997. The unconditional standard deviation of daily percentage changes in the zloty/U.S. dollar rate is estimated at 0.246 per day in 1996 or 3.94 in annualized terms. The corresponding standard deviation for 1997 is 0.548 per day or 8.77 in annualized terms, which makes for a statistically significant increase at any reasonable level.

62. In developed currency markets, simple autoregressive models have been found to satisfactorily describe the evolution of currency risk. But when applying those models to the Polish zloty surprisingly little evidence of volatility persistence, and thus predictability, is found. A shock to volatility in Poland is found to die out after just one day, whereas the volatility shock in a typical developed currency market lasts one to two weeks.

63. The lack of persistence in historical zloty volatility implies that autoregressive models say little about future volatility, and it motivates an examination of the predictive power of zloty currency derivatives. While the low derivatives trading volume hinders formal analysis, casual investigation shows that the forward-looking volatility measures implicit in observed currency option prices might help predict changes in zloty spot rate volatility. It is tentatively concluded that once derivatives markets develop further in Poland the monitoring of currency option prices should prove useful in Fund surveillance work.

²⁰ Prepared by Peter Christoffersen.

B. Zloty Spot Rate Volatility

Measuring historical zloty volatility

64. This section analyzes the developments in zloty volatility during the turbulence in international capital markets over the past two-plus years. The historical movements of the zloty within its +/- 7 percent band are depicted in Figure 6.

65. Volatility is inherently unobserved and must therefore be modeled and estimated. Before doing so it is necessary to establish a few pieces of notation. Let Y_t be defined as (100 x) the logarithmic zloty per U.S.dollar exchange rate at time t, and let y_t be the same observation after subtracting the conditional expectation based on all previous observations of Y_t ,

$$y_t \equiv Y_t - E(Y_t|Y_{t-1}, Y_{t-2}, \dots),$$

where $E(Y_t|Y_{t-1}, Y_{t-2}, \dots)$ is to be estimated. For speculative prices such as exchange rates the most widely used model by far is the simple random walk model,

$$E(Y_t|Y_{t-1}, Y_{t-2}, \dots) = Y_{t-1}.$$

In the case of Poland which has a crawling peg regime, a more appropriate model is,

$$E(Y_t|Y_{t-1}, Y_{t-2}, \dots) = \mu + Y_{t-1},$$

where μ is a drift term capturing the monthly crawl in the peg equal to one percent over 1996 and 1997. Standard inference not reported here reveals that the random walk plus drift model yields a good description of the zloty, thus the unpredictable change in the exchange rate will be defined as $y_t = Y_t - Y_{t-1} - \mu$.

66. The simplest measure of volatility is unconditional variance which is consistently estimated by

$$\text{Var}(y_t) = \frac{1}{T} \sum_{t=1}^T y_t^2$$

Estimating the unconditional variance for the zloty per U.S. dollar from May 1995 to January 1998 yields an estimate of .424 per day or 6.78 in annualized terms as depicted in the top-left panel of Figure 7.²¹

²¹ The daily standard deviation is annualized by multiplying by $\sqrt{256}$, the number of active trading days in a year.

Testing if volatility has increased

67. Using unconditional variance estimates it is possible to test whether volatility has increased significantly in 1997. The unconditional standard deviation of daily percentage changes in the zloty/U.S. dollar rate is estimated at .246 per day in the year 1996 or 3.94 in annualized terms. The corresponding standard deviation for the year 1997 is .548 per day or 8.77 in annualized terms. Under full ideal conditions the standard variance ratio test can be written

$$\hat{h}_{97} / \hat{h}_{96} \sim F(n_{97}-1, n_{96}-1)$$

where \hat{h}_{97} is the estimate of variance, and n_{97} is the number of observations in 1997. The ratio of variance in 1997 to 1996 is equal to 4.95 which is significantly different from 1 at any reasonable level. It appears fair to conclude that the policy objective of higher exchange rate volatility, which would cause risk-adjusted dollar returns on Polish debt to fall, was achieved by the National Bank of Poland in 1997.

Tracking volatility using autoregressive models

68. Rather than relying on unconditional variances when tracking exchange rate risk over time, a more precise concept is *conditional* variance which gives a measure of today's volatility given the information in all past observations in the sample. Generically one can write

$$\text{Var}_{t-1}(y_t) \equiv E[y_t^2 | y_{t-1}, y_{t-2}, \dots].$$

69. One of the simplest functions available is the K-day moving average of squares with constant weights equal to 1/K, call it MAV(K),

$$E[y_t^2 | y_{t-1}, y_{t-2}, \dots] = \frac{1}{K} \sum_{i=1}^K y_{t-i}^2$$

70. The MAV(21) for Poland is depicted in the top-right panel in Figure 7. The number of days, K, is set to 21 which is the average number of trading days in a month, and the estimate is annualized as before. Unfortunately, MAV models tend to exaggerate volatility by imposing persistence when no persistence is really present. The squared-box type shapes in Figure 7 arise because one extreme observation gets equal impact (equal to 1/21) 21 days onwards. Despite this drawback, the MAV models are frequently applied by currency traders in financial markets.

A slightly more sophisticated model, often favored by practitioners in the risk management industry, is the exponential smoothing (ES) model of the squares, which is an infinite moving average with exponentially declining weights,

$$E[y_t^2 | y_{t-1}, y_{t-2}, \dots] \equiv \sigma_t^2 = (1-\lambda) \sum_{i=0}^{\infty} \lambda^i y_{t-1-i}^2 = \lambda \sigma_{t-1}^2 + (1-\lambda) y_{t-1}^2.$$

The ES model underlies the Value-at-Risk measures recommended in J.P. Morgan's (1996) RiskMetrics system for market risk management. We follow J.P. Morgan's recommendation and set the smoothing parameter, $\lambda=.94$. The resulting, quite persistent volatility path is depicted in the bottom-left panel of Figure 7.

71. The benchmark time-series model in the academic literature for estimating and forecasting time varying volatility is Bollerslev's (1986) GARCH(1,1) model, which can be written recursively as

$$E[y_t^2 | y_{t-1}, y_{t-2}, \dots] \equiv h_t = \omega + \alpha y_{t-1}^2 + \beta h_{t-1}.$$

The GARCH(1,1) volatility also has a moving average interpretation; the above recursion can be written as

$$h_t = \frac{\omega}{1-\beta} + \alpha \sum_{i=0}^{\infty} \beta^i y_{t-1-i}^2.$$

For the zloty, the GARCH estimates are $\alpha = .28$ and $\beta = .42$, and the resulting much less persistent path of volatility is given in the bottom-right panel of Figure 7.

72. It is evident from the equations above that the volatility models are all particular moving averages of past squared exchange rate movements. When tracking estimates from the unconditional, the MAV(K), the GARCH(1,1) and the ES models in Figure 7 several events stand out. First, the sharp peak in volatility around July 9, 1997 coincided with the turbulence in the Thai baht. Second, the adjustment of the band in December 1995 evident in Figure 6 is visible in the volatility figure (Figure 7) but is completely dominated by the peak in July 1997. Third, the turbulence in South East Asia in the fall of 1997 is evident but that episode is also dominated by the jump in July.

73. Despite certain similarities, notice also the sharply different patterns of volatility from the different models. Compared to developed currency markets, and compared to the MAV(K) and ES models, persistence in volatility in the GARCH model is estimated to be relatively weak. The standard measure of persistence is $\alpha+\beta$ which is commonly measured to be around 0.95 for hard currency cross rates. Persistence as measured by $\alpha+\beta$ gives a rough measure of the rate of decay of a shock to volatility.²² For the zloty per dollar rate we estimate $\alpha+\beta$ to be around .70. In fact, the correlelogram of the squares— not reported here— implies that an ARCH(1) model will suffice. The ARCH(1) model is characterized by having $\beta=0$, and a shock to volatility disappearing after just one day.²³

²² To be exact, the squared exchange rate movements, y_t^2 , in a GARCH(1,1) model can be written as an ARMA(1,1) model where the autoregressive parameter equals $\alpha+\beta$. Similarly the ES model can be written as a random walk in y_t^2 with MA(1) innovations.

²³ See Christoffersen (1998) for a comparison of volatility models for risk management.

74. As can be seen by inspecting the formulae above, the ES model is a special case of GARCH(1,1) where $\beta=\lambda$ and $\alpha=1-\lambda$ which implies $\alpha+\beta=1$. Thus the persistence of the ES model is forced to be one which means that a shock permanently changes volatility. Thus the highly persistent volatility pattern in the bottom-left panel of Figure 7 turns out to be an artifact of that particular model rather than a feature of the data itself. The 21-day moving average model, MAV(21), in Figure 7 by nature imposes persistence lasting for 21 days and then immediately dying out, accounting for the squared-box patterns.

C. Analyzing OTC Currency Options on the Zloty

75. The lack of persistence in zloty exchange rate volatility in the autoregressive GARCH models implies that the past sequence of exchange rate movements does not contain much information about future volatility. The lack of persistence thus motivates a search for alternative information which might have more predictive power. This section asks whether currency option prices can signal future changes in currency volatility. The advantage of using option prices over historical spot rates to predict future volatility is the inherent forward looking property of option prices. In developed markets, options as opposed to interest rates and forward rates allow computation of the entire expected distribution and thus estimation of extreme event probabilities, such as large depreciations.²⁴ Early warning systems of currency crises using options prices have been successfully applied by Campa and Chang (1996) to the ERM crises of 1991-94. While no exchange traded options exist for the zloty at present, contracts get traded over the counter (OTC). The quality of the analysis will of course depend on the available price data: more liquid markets, and a wider range of strike prices yield better estimates. Recent work by Campa, Chang and Reider (1997) suggest that OTC option prices on fully convertible currencies are indeed applicable to this kind of analysis. As the Polish zloty is not yet fully convertible, Polish option markets are not yet developed enough that the entire underlying distribution can be extracted. However, monitoring options prices and more precisely their implied volatility can still help to provide insight into the market's expectation of future zloty exchange rate movements.

The trading of Polish currency options

76. This section outlines the main features of currency option trading on the zloty.²⁵ The main banks and brokers in Poland have quotes on zloty per U.S. dollar and zloty per DM options on their screen daily. However, activity is typically limited to around 1-2 trades per week per bank, and the bid-ask spread is quite wide, around 10 percent for 1-month and 30 percent for 1-year maturity for a strike price at the forward rate. There is no Polish interbank market for currency options yet, so most trades are between banks and their corporate clients. Polish market participants mention that offshore brokers in London are the most active trading

²⁴ See Söderlind and Svensson (1997) for a survey of these methods.

²⁵ See Malecki (1997) for an overview of developments in Polish currency and options markets.

zloty options as banks in Poland are restricted to trading with local clients. Interestingly, a major London broker notes that London firms typically get their quotes from the main banks *in* Poland. Due to the lack of external convertibility of the zloty, all options as well as synthetic forwards are cash settled in U.S. dollars upon expiration. The market participants believe that once the zloty becomes fully convertible, activity in zloty options will increase considerably. While the markets at present are not active enough to justify estimating the entire implied density, it is reasonable to study the volatility implied in quoted options prices.

Basic currency option pricing theory

77. The standard theory of currency option pricing assumes that the underlying exchange rate follows a geometric Brownian motion and relies on risk free interest rates for the domestic currency (dollar), r , and for the foreign currency (zloty), r_f . Analogous to the well known Black-Scholes formula, the price of a European call option, c , on the zloty per dollar exchange rate, S , is given by the Garman and Kohlhagen (1983) formula (GK),

$$c = S \exp(-r_f(T-t))N(d_1) - X \exp(-r(T-t))N(d_2),$$

where $T-t$ is the number of days until the option expires, $N(\bullet)$ is the standard Normal c.d.f.,

$$d_1 = \frac{\ln(S/X) + (r - r_f + \sigma^2/2)(T-t)}{\sigma\sqrt{T-t}}, \text{ and } d_2 = d_1 - \sigma\sqrt{T-t},$$

where σ is the volatility of the exchange rate.

78. Focusing on options with a strike price, X , equal to the forward rate, $F=X$, and applying the spot forward parity, $F = S \exp(r-r_f)(T-t)$, one can simplify the pricing relationship to

$$c = \exp(-r(T-t))F[2N(\sigma\sqrt{T-t}/2) - 1].$$

This simple expression is explicitly invertible, and can be solved for the volatility term as

$$\sigma = \frac{2}{\sqrt{T-t}}N^{-1}\left(\frac{c}{2F}\exp(r(T-t)+\frac{1}{2})\right)$$

79. If the GK formula were really true, at all points in time and for all contracts, one would get exactly the same volatility, as a constant volatility, σ , is assumed. However, the GK formula does not hold exactly in practice, and we can define

$$\tilde{\sigma}(c,F,r,T-t) = \frac{2}{\sqrt{T-t}}N^{-1}\left(\frac{c}{2F}\exp(r(T-t)+\frac{1}{2})\right)$$

to be the *implied volatility* which might vary over time, and depend on the call price, c , the forward rate, F , the risk free rate, r , and the days to expiration, $T-t$, of the option. Only in the case where the GK formula was exactly true would the left hand side be constant across time and option contracts.

80. In OTC markets traders do not quote prices, c , but in fact use the GK formula to simply quote the option price in terms of its implied volatility, $\tilde{\sigma}$. Notice that there is a one-to-one mapping between $\tilde{\sigma}$ and c , so there is no loss in generality from quoting $\tilde{\sigma}$ rather than c . The advantage of quoting $\tilde{\sigma}$ is that the quote does not have to be continuously updated as the underlying spot rate or forward rate changes. Of course, quoting $\tilde{\sigma}$ does not imply that the traders believe the GK formula to hold; it is simply a market convention.

Interpreting observed implied volatilities

81. Data on implied volatilities from currency options have been obtained from the dealer room of a major investment bank in Warsaw. Figure 8 gives the implied volatility from quoted mid-rate prices on 1-month at-the-forward call options on the zloty per dollar exchange rate. Also depicted is the historical volatility as measured by the bank. As is standard but somewhat misleading (see Section II), volatility is reported as a standard deviation of a 21-day moving average, MAV(21), and scaled by $\sqrt{256}$ to give an annualized number. As discussed above, historical volatility is overstated in the figure due to the application of the MAV technique. This makes the changes in implied volatility seem trivial. Despite this distraction, the key thing to note is whether implied volatility changes *before* the estimate of historical volatility, suggesting that implied volatility *leads* the actual and will be useful for exchange rate surveillance. Unfortunately, the evidence in Figure 8 is not conclusive. In the earlier part of the sample (1996), implied volatility seems to be *lagging* historical volatility suggesting that traders quote option prices based on historical numbers for volatility. However, later in the sample (1997), volatility in some instances does seem to move prior to surges in actual volatility indicating the usefulness of option prices as a leading indicator once markets develop further.

D. Summary

82. In developed currency markets, simple autoregressive models have been found to satisfactorily describe the evolution of currency risk; but when applying those models to the Polish zloty surprisingly little evidence of volatility persistence, and thus predictability, is found. The lack of predictive power of autoregressive models motivates the question whether currency options can signal future changes in currency volatility? While the low derivatives trading volume hinders formal analysis, casual investigation shows that the forward looking volatility measures implicit in observed currency option prices might help predict forthcoming changes in zloty spot rate volatility once markets develop further.

| Reported vacancies | 54 | 29 | 23 | 22 | 25 | 21 | 14 |

Source: Data provided by the Polish authorities.

1/ The working age for men/women is defined to be between the ages of 18 and 64/59.

2/ Employment statistics exclude workers doing military service, working in defense and public-safety related institutions, living abroad, or serving a jail sentence. These workers, however, are classified as part of the active labor force. Taking into account the different statistical treatment accorded to these workers, the calculated unemployment rate was close to zero through 1989.

Source: Data provided by the Polish authorities, and staff calculations.

1/ Final consumption expenditure.

2/ Gross fixed capital formation.

3/ According to the Polish version of the NACE-EKD classification system. Until 1993 indices include VAT; 1994-95 excluding VAT, including excise tax; from 1996 onwards excluding VAT and excise tax.

4/ The range of prices administered by the state has fallen over time. In 1997: the price of spirit alcohol was controlled; furnace fuels (coal, wood) are no longer controlled; control of medicine prices applies to a limited range of domestically produced pharmaceutical goods; the price of natural gas delivered through municipal installations is controlled; the state sets maximum prices for central heating and hot water--the index measures actual prices in force, which are sometimes below the state-set maximum.

Source: Data provided by the Polish authorities; and staff calculations.

1/ The NBP refinance rate and the deposit and lending rates are end-period values, while all the other rates are monthly averages.

2/ From January 1996, the refinancing rate for central investment loans guaranteed by the State Treasury is equal to the Lombard rate (shown in the table); for other refinancing loans the rate is 1 point higher.

3/ One-day reverse repo rate in 1994-95, 14-day reverse repo rate in 1996.

4/ Midpoint of the range of rates offered by principal commercial banks.

5/ Prime lending rate on low risk loans.

6/ Warsaw interbank offered rate.

7/ Interest rate on zloty instrument minus interest rate on equivalent U.S. dollar instrument minus annualized rate of crawl.

Sources: Data provided by the Polish authorities and staff estimates.

1/ Data are on a cash basis except for state budget expenditure, which is on a domestic commitments basis. As of 1994, the data are compiled according to GFS. Hence, 1994-96 data may not be strictly comparable with previous years. The state budget comprises central government and regional authorities.

2/ Expenditure includes net lending

Sources: Data provided by the Polish authorities and staff estimates.

1/ Data are on a cash basis except for state budget expenditure, which is on a domestic commitments basis. As of 1994, the data are compiled according to GFS. Hence, 1994-96 data may not be strictly comparable with previous years. The state budget comprises central government and regional authorities.

Table 27. Poland: Exchange Rate Developments

| Period | Exchange Rate Policy | Action | Comments |
|---------------|---|---|---|
| Before 1990 | Multiple exchange rates, adjustable peg to a basket of currencies | Frequent and substantial devaluations | |
| Jan. 1, 1990 | Fixed exchange rate system | Unification of official and black market rates Devaluation (46.2 percent) | Exchange rate: Zl 9,500 per U.S. dollar |
| May. 17, 1991 | Fixed exchange rate system | Devaluation (16.8 percent against the dollar). Shift from a dollar peg to a basket peg | Exchange rate: Zl 11,100 per U.S. dollar. Basket includes: U.S. dollar (45 percent), deutsche mark (35 percent), pound sterling (10 percent), French franc (5 percent), Swiss franc (5 percent) |
| Oct. 15, 1991 | Preannounced crawling peg | Rate of crawl announced: 1.8 percent per month (Zl 9 per day) | |
| Feb. 25, 1992 | Preannounced crawling peg | Devaluation (12.0 percent against the basket). Rate of crawl: 1.8 percent per month (Zl 11 per day) | Exchange rate: Zl 13,360 per U.S. dollar |
| Jul. 10, 1992 | Preannounced crawling peg | Rate of crawl: 1.8 percent per month (Zl 12 per day) | Basket unchanged Technical adjustment made |
| Aug. 27, 1993 | Preannounced crawling peg | Devaluation (8.1 percent against the basket) Rate of crawl reduced: 1.6 percent per month (Zl 15 per day) | Basket unchanged |
| Sep. 13, 1994 | Preannounced crawling peg | Rate of crawl reduced: 1.5 percent per month | Basket unchanged |
| Nov. 30, 1994 | Preannounced crawling peg | Rate of crawl reduced: 1.4 percent per month | Basket unchanged |
| Jan. 1, 1995 | Redenomination | One new zloty equal to 10,000 old zlotys | |
| Feb. 15, 1995 | Preannounced crawling peg | Rate of crawl reduced: 1.2 percent per month | Basket unchanged |
| Mar. 6, 1995 | Preannounced crawling peg | Increase in the spread for NBP/banks transactions to +/- 2 percent around the NBP mean rate | Basket unchanged |
| May. 16, 1995 | Preannounced crawling peg, with the fixing rate fluctuating within +/- 7 percent around central parity | Initial appreciation of fixing rate to 5 percent below central parity (3 percent below NBP buying rate). Rate of crawl: 1.2 percent per month | Basket unchanged |
| Sep. 8, 1995 | Preannounced crawling peg, with the fixing rate fluctuating within +/- 7 percent around central parity | Further appreciation to 6 percent below central parity. Rate of crawl: 1.2 percent per month | Basket unchanged |
| Dec. 22, 1995 | Preannounced crawling peg, with the fixing rate fluctuating within +/- 7 percent around central parity | Official appreciation of the central parity by 6 percent, initial appreciation of the fixing rate to 2.5 percent below the new central parity. Rate of crawl: 1.2 percent per month | Basket unchanged |
| Jan. 8, 1996 | Preannounced crawling peg, with the fixing rate fluctuating within +/- 7 percent around central parity | Rate of crawl reduced: 1 percent per month | Basket unchanged |
| Feb. 25, 1998 | Preannounced crawling peg, with the fixing rate fluctuating within +/- 10 percent around central parity | Rate of crawl reduced: 0.8 percent per month | Basket unchanged |

Table 28. Poland: Effective Exchange Rates, 1992-97

(Quarterly average indices, January 1992 = 100)

| | | Real Effective Exchange Rate | | Nominal Effective Exchange Rate |
|-------|-----|------------------------------|----------------|---------------------------------|
| | | Wage Based 1/ | Price Based 2/ | |
| 1992: | I | 94.3 | 96.5 | 94.9 |
| | II | 83.1 | 92.9 | 83.8 |

Table 41. Poland: Protectionist Measures Introduced by the European Union, March 1992– January 1998

| Product | Type of Measure | Status | Description | Introduction Date |
|---|--------------------|--------------------|---|-------------------|
| Silicon | Dumping | Provisional duties | EU imposed provisional duties of 32 percent on imports of silicon after Commission determined that dumping at margins up to 61.5 percent had | 7/6/92 |
| Frozen strawberries and black currants | Subsidies | Final ruling | EU Commission decided to impose countervailing duties in amount of the difference between Polish prices and EU minimum import prices on imports of frozen strawberries and black currants. | 10/1/92 |
| Seamless steel tubes | Dumping | Preliminary ruling | EU imposed provisional antidumping duties on imports of seamless steel tubes (10.8 percent). They were imposed for four months pending an inquiry. | 11/15/92 |
| Steel tubes | Dumping | Preliminary ruling | EU made preliminary affirmative determination in dumping case involving steel tubes. | 11/15/92 |
| Hematite pig iron | Dumping | Investigation | EU initiated a dumping investigation of imports of hematite pig iron. | 12/9/92 |
| Ferro-silicon | Dumping | Final ruling | EU council imposed definitive antidumping duties of 32 percent on imports of ferro-silicon. | 12/15/92 |
| Steel tubes | Dumping | Extension | EU extended for two months preliminary antidumping duties on imports of steel tubing. | 3/8/92 |
| Frozen blackcurrants, strawberries | Minimum prices | Amendment | EU amended a regulation imposing minimum prices on imports of frozen blackcurrants and strawberries. | 4/1/92 |
| Live animals and fresh meat | Import prohibition | Introduction | EU imposed import prohibition on animals and fresh meat because of cases of foot-and mouth disease in Italy. | 5/10/93 |
| Urea | Dumping | Investigation | EU Commission initiated a dumping investigation of imports of urea. | 5/13/93 |
| Urea ammonium nitrate | Dumping | Investigation | EU initiated a dumping investigation of imports of urea ammonium nitrate. | 5/13/93 |
| Steel tubes | Dumping | Final ruling | EU imposed definitive antidumping duties on imports of steel tubes (10.8 percent), duties effective 5/15/93. | 5/15/93 |
| Seamless pipes and tubes of iron and steel | Dumping | Final ruling | EU Commission imposed definitive antidumping duties (and there was a price undertaking) on imports of seamless pipes and tubes of iron and steel (11.7 percent). | 5/15/93 |
| Cherries | Minimum price | Introduction | EU Council agreed to introduce minimum import prices on cherries. | 7/19/93 |
| Silicon carbide | Dumping | Final ruling | EU imposed a duty of 8.3 percent. | 4/13/94 |
| Pig iron (hematite) | Dumping | Final ruling | EU imposed on rate of duty to equalize the price to ECU 149 per ton. | 7/16/94 |
| Urea ammonium nitrate solution | Dumping | Final ruling | EU imposed provisional duties to equalize the price to ECU89 per ton (alternatively a specific duty of ECU 19 to 22 ECU per ton could be imposed). | 7/1/94 |
| Zinc | Dumping | Investigation | EU Commission initiated a dumping investigation of imports of zinc. | 6/9/95 |
| Wooden pallets | Dumping | Investigation | EU Commission initiated a dumping investigation on imports of wooden pallets. | 7/13/95 |
| Zinc | Dumping | Final ruling | EU Commission imposed provisional (for six months) antidumping duties on imports of unwrought, unalloyed zinc (14.4 percent). | 3/25/97 |
| Ferro-silicon | Dumping | Periodical review | EU Commission initiated periodical anti-dumping reviews on imports of ferro-silicon. | 7/4/97 |
| Zinc | Dumping | Final ruling | EU Commission imposed antidumping duties on imports of unwrought, unalloyed zinc (10.6 percent) for those Polish producers which follow minimum price agreements. | 9/22/97 |
| Seamless pipes and tubes of iron or non-alloy steel | Dumping | Final ruling | After periodical review, EU Commission imposed antidumping duties on imports of seamless pipes and tubes of iron or non-alloy steel (30.1 percent) for five years, except for imports under agreed volume and price quotas. | 11/17/97 |
| Wooden pallets | Dumping | Final ruling | Minimum prices and antidumping duties (6.3 percent) on imports of flat wooden pallets; price agreement with Polish producers of so called 'wooden europallets'. | 11/24/97 |
| Hard-board | Dumping | Investigation | EU Commission initiated a dumping investigation on imports of hard-board. | |
| Milk and milk products | Import prohibition | Introduction | EU imposed import prohibition on milk and milk products because of not meeting sanitary requirements by Polish dairy companies. | 12/1/97 |
| String for sheaf-binders | Dumping | Investigation | EU Commission initiated a dumping investigation on imports of string for sheaf-binders. | 1/2/98 |

1/ Excluding cooperative banks and banks in liquidation or bankruptcy.

Table 45. Poland: Key Banking Prudential Regulations
(as of January 1, 1998)

Capital

- Minimum capital: ECU 5 million (about Zl 19 million, US\$5.5 million)
- Minimum capital adequacy ratio: in general 8 percent; but 15 percent for newly started banks during the first year, and 12 percent during the second year

Deposit insurance

- Explicit insurance was available through state-owned commercial banks but not private banks until February 1995, when the Bank Guarantee Fund came into force. Full coverage is up to ECU 1,000 (90 percent coverage up to ECU 5,000) per account in private banks, and unlimited in state-owned banks (PKO BP, PKO SA, and BGZ up to end-1999).

Loan loss provisioning

- Assets past due between 30 and 90 days ("substandard") require a 20 percent provision.
- Those past due between 91 and 180 days ("doubtful") require a 50 percent provision.
- Those past due more than 180 days ("lost") require a 100 percent provision.

Lending limits

- Large exposures are defined as those debtors whose loans exceed 10 percent of capital in the aggregate. Aggregate large exposures are limited to 800 percent of capital.
- Aggregate direct lending to bank directors, managers, and members of their statutory bodies is limited to 10 percent of capital (25 percent in cooperative banks).
- Aggregate lending (including purchase of bonds and issue of guarantees) to insiders, i.e., entities linked by capital or organization with the bank and having joint economic risk with the bank, is limited to 25 percent of capital.

Capital concentration

- The amount of shares and stakes acquired by a bank in a non-bank entity is limited to 15 percent of capital.
